GLUCOCORTICOID RECEPTOR MODULATORS

5 FIELD OF THE INVENTION

The present invention relates to non-steroidal compounds which are selective modulators of steroid receptors, in particular, the glucocorticoid receptor. In particular, the present invention is directed to compounds and methods for using such compounds to treat mammals requiring glucocorticoid receptor modulation.

10

BACKGROUND OF THE INVENTION

Glucocorticoids are lipid soluble hormones synthesized in the adrenal cortex (Neville and O'Hare, *The Adrenal Gland*, James, Ed. New York, Raven, 1-65, (1979)). These molecules readily pass through cell membranes and enter the cytoplasm of target tissues, where they bind to glucocorticoid receptors sequestered in the cytoplasm by complexation with heat shock proteins. Upon binding of the hormone to its receptor, the receptor undergoes a conformational change which results in dissociation of heat shock proteins, and translocation of the ligand bound glucocorticoid receptor into the nucleus where it can either initiate or repress specific gene transcription. Transcriptional activation occurs when the ligand bound receptor complex homodimerizes, and the homodimeric receptor ligand complex binds to chromosomal deoxyribonucleic acid (DNA) at sequence specific sites in the promoter region of regulated genes (Beato, *Cell*, 56, 335-344 (1989); and Yamamoto, *Annu. Rev. Genet.*, 19, 209-215 (1989)). Excesses or deficiencies of these ligands can have profound physiological consequences. As an example, glucocorticoid excess results in Cushing's Syndrome, while glucocorticoid insufficiency results in Addison's Disease.

Biologically relevant glucocorticoid receptor agonists include cortisol and corticosterone. Many synthetic glucocorticoid receptor agonists exist including dexamethasone, prednisone and prednisilone. By definition, glucocorticoid receptor antagonists bind to the receptor and prevent glucocorticoid receptor agonists from binding and eliciting GR mediated events, including transcription. RU486 is an example of a non-selective glucocorticoid receptor antagonist.

Type II diabetes (also referred to as non insulin-dependent Diabetes Mellitus) is a debilitating disease characterized by an abnormal elevation of blood glucose levels driven by three factors: increased hepatic glucose production, inadequate clearance of glucose via insulin mediated pathways, and decreased uptake of circulating glucose by tissues (DeFronzo, *Diabetes Review* 5(3), 177-269, (1997)). Administration of agents that decrease hepatic glucose production are a fundamental approach to controlling blood glucose (De

Feo et al., *Am. J. Physiol.* 257, E35-E42 (1989); Rooney, et al., *J. Clin. Endocrinol. Metab.* 77, 1180-1183 (1994); and Dinneen et al., *J. Clin. Invest.*, 92, 2283-2290 (1993)).

Glucocorticoids have been shown to have major influences on glucose production.

Glucocorticoid excess aggravates established diabetes while glucocorticoid deficiency

5 reduces blood glucose and improves glucose control in diabetic mice (Boyle, *Diabetes Review*, 1(3), 301-308, (1993); Naeser, *Diabetologia*, 9, 376-379 (1973); and Solomon et al., *Horm. Metab. Res.*, 9, 152-156 (1977)). The underlying mechanism responsible for these effects is the glucocorticoid-induced upregulation of key hepatic enzymes required for gluconeogenesis (Exton et al., *Recent Prog. Horm. Res.*, 26, 411-457 (1970); and Kraus-

10 Friedmann, *Physiol. Rev.*, 64, 170-259 (1984)).

Among the genes that glucocorticoids up-regulate are several genes that play key roles in gluconeogenesis and glycogenolysis, particularly phosphoenolpyruvyl

carboxykinase (PEPCK) and glucose-6-phosphatase (Hanson and Patel, *Adv. Enzymol.*,

Meister, Ed. New York, John Wiley and Sons, Inc., 203-281 (1994); and Argaud et al.,

15 *Diabetes* 45, 1563-1571 (1996)). Mifepristone (RU486), a potent GR antagonist reduces messenger ribonucleic acid (mRNA), levels of PEPCK and glucose-6-phosphate in the liver, and causes a 50% reduction of plasma glucose levels in obese diabetic db/db transgenic

mice (Friedman et al., *J. Biol. Chem.* 272(50), 31475-31481 (1997)). While steroid-based

20 GR antagonists have been useful in demonstrating efficacy for in vivo glucose lowering effects, the utility of such agents is limited due to side effects resulting from potent cross-reactivity with other steroid receptors, in particular progesterone receptor (PR) and

mineralocorticoid receptor (MR). US 5,929,058 discloses a method for treating type II

diabetes by administering a combination of steroidal-agents that exhibit mineralocorticoid

25 agents that function as glucocorticoid receptor (GR) antagonists represent a novel approach to controlling type II diabetes.

Other examples of proteins that interact with the glucocorticoid receptor are the transcription factors AP-1 and NF κ -B. Such interactions result in inhibition of AP-1- and

30 NF κ -B- mediated transcription and are believed to be responsible for some of the anti-inflammatory activity of endogenously administered glucocorticoids. In addition,

glucocorticoids may also exert physiologic effects independent of nuclear transcription.

Glucocorticoid selective non-steroidal agents that antagonize functional activity mediated by the glucocorticoid receptor may be useful for treating mammals suffering from

type II diabetes and for treating symptoms of type II diabetes including hyperglycemia,

35 inadequate glucose clearance, obesity, hyperinsulinemia, hypertriglyceridemia and high

circulating glucocorticoid levels. In addition to diabetes, glucocorticoid receptor

modulators are useful to treat diseases such as obesity, Syndrome X, Cushing's Syndrome, Addison's disease, inflammatory diseases such as asthma, rhinitis and arthritis, allergy,

autoimmune disease, immunodeficiency, anorexia, cachexia, bone loss or bone frailty, and wound healing.

US Patent No. 5,929,058 discloses a method for treating type II diabetes by administering a combination of steroidal-agents that exhibit mineralcorticoid receptor agonist activity and glucocorticoid receptor antagonist activity.

Although there are glucocorticoid receptor therapies in the art, there is a continuing need for and a continuing search in this field of art for selective glucocorticoid receptor therapies. Thus, the identification of non-steroidal compounds which have specificity for one or more steroid receptors, but which have reduced or no cross-reactivity for other steroid or intracellular receptors, is of significant value in this field.

Methods for Radioligand Binding Studies with Human Glucocorticoid and Progesterone

Receptor Cytosol

³[H]-dexamethasone (TRK 645) hereafter referred to as ³[H]-dex was purchased from Pharmacia Amersham, Uppsala, Sweden. Dexamethasone hereafter referred to as dex was purchased from SIGMA. The Costar 96-well polypropylene plates (3794 or 3365) were purchased from Life Technologies AB, Täby, Sweden. The GF/B filter (1450-521), filter cassette (1450-104), MeltiLex scintillating wax (1450-441), sample bag (1450-42), Microbeta™ 1450-PLUS and Microsealer 1495-021 were all purchased from Wallac Oy, Turku, Finland. Human glucocorticoid receptors were extracted from Sf9 cells infected with a recombinant baculovirus transfer vector containing the cloned hGR genes. Recombinant baculovirus was generated utilizing the BAC-TO-BAC expression system (Life Technologies) in accordance to instruction from the supplier. The hGR coding sequences were cloned into a baculovirus transfer vector by standard techniques. The recombinant baculoviruses expressing hGR were amplified and used to infect Sf9 cells. Infected cells were harvested 48hrs post infection. The receptors were extracted from the cell pellet with a phosphate buffer (1mM EDTA, 20mM KPO₄ (pH8), 8.6% Glycerol, 12mM MTG, 20mM Na₂MoO₄). The concentration of hGR in the extract was measured as specific ³[H]-dex binding with the G25-assay as described in J. Steroid Biochem. Molec. Biol. 50, No. 5/6, 313-318, 1994 and estimated to approximately 25nM. The extract was aliquoted and stored at -70°C.

The filter binding assay: Dilution series of the test compounds and dex as reference were made from 10mM (1mM dex) stock solutions in DMSO. 10μl of the dilutions was added in duplicates to the wells. The cell extracts were diluted 10 fold in EPmo + MTG buffer (1mM EDTA, HPO₄ 20mM (pH8), 6mM MTG). The diluted extract was added to the wells (110μl). ³[H]-dex were diluted from the stock solution to 10-10.8nM in EPmo + MTG buffer. 110μl of the diluted ³[H]-dex were added to the wells. The final concentration of hGR in the experiment was estimated to 1nM. All preparations were made in ambient temperature (20-25°C) on ice and with +4°C tempered buffers. The plates were incubated over night at +4°C (15-20 hours).

The incubation was stopped by filtration through GF/B filter on the Tomtec Cellharvester. The filtration on the Tomtec Cellharvester was programmed as follows: 1) Preparation before filtration with EP buffer (1mM EDTA 20mM HPO₄ (pH8)) 2x[Wash/Asp 0.6sec., Asp 0.5sec.] ; 2) Prewet of GF/B filter with EP + PEI buffer (EP

buffer, 0.3% Polyethylenimine) [Asp 0.8sec.]; 3) Filtration/harvesting of the 96-well incubation plate 3x[Wash/Asp 0.6sec., Asp 0.5sec.]. The GF/B filter was dried for at least 1 hour at 65°C. A MeltiLex scintillation wax was melted onto the filter with the Microsealer. The filter was placed in a samplebag, which was thereafter trimmed with scissors to fit the filter cassette. The cassette were placed in the Microbeta and measured for 1min /position, returning cpm (corrected counts per minute).

For compounds able to displace the $^3\text{[H]}$ -dex from the receptor an IC_{50} -value (the concentration required to inhibit 50% of the binding of $^3\text{[H]}$ -dex) was determined by a non-linear four parameter logistic model;

$$b = ((b_{\max} - b_{\min}) / (1 + (I / \text{IC}_{50})^S)) + b_{\min} I$$

where b is the amount of bound ligand as measured by tritium counting, I is added concentration of binding inhibitor, IC_{50} is the concentration for inhibitor at half maximal binding and S is a slope factor (Haggblad, J., Carlsson, B., Kivelä, P., Siitari H., (1995) Biotechniques 18, 146-151). For determinations of the concentration of $^3\text{[H]}$ -dex in the solutions, regular scintillation counting in a Wallac Rackbeta 1214 was performed using the scintillation cocktail Supermix™ (Wallac).

The Microbeta-instrument generates the mean cpm (counts per minute) value / minute and corrects for individual variations between the detectors thus generating corrected cpm values. It was found that the counting efficiency between detectors differed with less than five percent.

A similar protocol was employed to measure affinity of the compounds of the present invention for progesterone receptor (PR).

Compounds of the present invention are active in the GR binding assay described above, and show selectivity for GR over PR, as indicated in Table 1.

35 Compounds of the present invention may exist as stereoisomers wherein,

asymmetric or chiral centers are present. These stereoisomers are "R" or "S" depending on the configuration of substituents around the chiral carbon atom. The terms "R" and "S" used herein are configurations as defined in IUPAC 1974 Recommendations for Section E, Fundamental Stereochemistry, Pure Appl. Chem., 1976, 45: 13-30. The present invention
5 contemplates various stereoisomers and mixtures thereof and are specifically included within the scope of this invention. Stereoisomers include enantiomers and diastereomers, and mixtures of enantiomers or diastereomers. Individual stereoisomers of compounds of the present invention may be prepared synthetically from commercially available starting materials which contain asymmetric or chiral centers or by preparation of racemic mixtures
10 followed by resolution well-known to those of ordinary skill in the art. These methods of resolution are exemplified by (1) attachment of a mixture of enantiomers to a chiral auxiliary, separation of the resulting mixture of diastereomers by recrystallization or chromatography and liberation of the optically pure product from the auxiliary or (2) direct separation of the mixture of optical enantiomers on chiral chromatographic columns.

15 Geometric isomers can also exist in the compounds of the present invention. The present invention contemplates the various geometric isomers and mixtures thereof resulting from the arrangement of substituents around a carbon-carbon double bond or arrangement of substituents around a ring. Substituents around a carbon-carbon double bond are designated as being in the Z or E configuration where the term "Z" represents substituents
20 on the same side of the carbon-carbon double bond and the term "E" represents substituents on opposite sides of the carbon-carbon double bond. The arrangement of substituents around a ring are designated as cis or trans where the term "cis" represents substituents on the same side of the plane of the ring and the term "trans" represents substituents on opposite sides of the plane of the ring. Mixtures of compounds where the substituents are
25 disposed on both the same and opposite sides of plane of the ring are designated cis/trans.

The term "pharmaceutically acceptable prodrugs" represents those prodrugs of the compounds of the present invention which are, within the scope of sound medical judgement, suitable for use in contact with the tissues of humans and lower animals with undue toxicity, irritation, allergic response, and the like, commensurate with a reasonable
30 benefit/risk ratio, and effective for their intended use, as well as the zwitterionic forms, where possible, of the compounds of the invention.

The term "prodrug" represents compounds which are rapidly transformed in vivo to a compound of formula (I-IV), for example, by hydrolysis in blood. A thorough discussion is provided in T. Higuchi and V. Stella, Pro-drugs as Novel Delivery Systems, Vol. 14 of
35 the A.C.S. Symposium Series, and in Edward B. Roche, ed., Bioreversible Carriers in Drug Design, American Pharmaceutical Association and Pergamon Press, 1987.

The term "pharmaceutically acceptable salt" represents those salts which are, within the scope of sound medical judgement, suitable for use in contact with the tissues of humans

and lower animals without undue toxicity, irritation, allergic response and the like, and are commensurate with a reasonable benefit/risk ratio. Pharmaceutically acceptable salts are well known in the art. For example, S. M. Berge, et al. describe pharmaceutically acceptable salts in detail in *J. Pharmaceutical Sciences*, 66:1-19 (1977). The salts can be prepared in situ during the final isolation and purification of the compounds of the invention, or separately by reacting the free base function with a suitable organic acid. Representative acid addition salts include acetate, adipate, alginate, ascorbate, aspartate, benzenesulfonate, benzoate, bisulfate, borate, butyrate, camphorate, camphersulfonate, citrate, cyclopentanepropionate, digluconate, dodecylsulfate, ethanesulfonate, fumarate, glucoheptonate, glycerophosphate, hemisulfate, heptonate, hexanoate, hydrobromide, hydrochloride, hydroiodide, 2-hydroxy-ethanesulfonate, lactobionate, lactate, laurate, lauryl sulfate, malate, maleate, malonate, methanesulfonate, 2-naphthalenesulfonate, nicotinate, nitrate, oleate, oxalate, palmitate, pamoate, pectinate, persulfate, 3-phenylpropionate, phosphate, picrate, pivalate, propionate, stearate, succinate, sulfate, tartrate, thiocyanate, toluenesulfonate, undecanoate, valerate salts, and the like. Representative alkali or alkaline earth metal salts include sodium, lithium, potassium, calcium, magnesium, and the like, as well as nontoxic ammonium, quaternary ammonium, and amine cations, including, but not limited to ammonium, tetramethylammonium, tetraethylammonium, methylamine, dimethylamine, trimethylamine, triethylamine, ethylamine, and the like.

The term "pharmaceutically acceptable carrier," as used herein, means a non-toxic, inert solid, semi-solid or liquid filler, diluent, encapsulating material or formulation auxiliary of any type. Some examples of materials which can serve as pharmaceutically acceptable carriers are sugars such as lactose, glucose and sucrose; starches such as corn starch and potato starch; cellulose and its derivatives such as sodium carboxymethyl cellulose, ethyl cellulose and cellulose acetate; powdered tragacanth; malt; gelatin; talc; excipients such as cocoa butter and suppository waxes; oils such as peanut oil, cottonseed oil, safflower oil, sesame oil, olive oil, corn oil and soybean oil; glycols; such a propylene glycol; esters such as ethyl oleate and ethyl laurate; agar; buffering agents such as magnesium hydroxide and aluminum hydroxide; alginic acid; pyrogen-free water; isotonic saline; Ringer's solution; ethyl alcohol, and phosphate buffer solutions, as well as other non-toxic compatible lubricants such as sodium lauryl sulfate and magnesium stearate, as well as coloring agents, releasing agents, coating agents, sweetening, flavoring and perfuming agents, preservatives and antioxidants can also be present in the composition, according to the judgment of the formulator.

The present invention also provides pharmaceutical compositions, which comprise compounds of the present invention formulated together with one or more non-toxic pharmaceutically acceptable carriers. The pharmaceutical compositions may be specially formulated for oral administration in solid or liquid form, for parenteral injection, or for

rectal administration.

Further included within the scope of the present invention are pharmaceutical compositions comprising one or more of the compounds of formula (I-IV) prepared and formulated in combination with one or more non-toxic pharmaceutically acceptable compositions. The pharmaceutical compositions can be formulated for oral administration
5 in solid or liquid form, for parenteral injection or for rectal administration.

The pharmaceutical compositions of this invention can be administered to humans and other animals orally, rectally, parenterally, intracisternally, intravaginally, intraperitoneally, topically (as by powders, ointments, or drops), buccally, or as an oral or
10 nasal spray. The term "parenteral" administration refers to modes of administration which include intravenous, intramuscular, intraperitoneal, intrasternal, subcutaneous and intraarticular injection and infusion.

Pharmaceutical compositions of this invention for parenteral injection comprise pharmaceutically acceptable sterile aqueous or nonaqueous solutions, dispersions,
15 suspensions or emulsions as well as sterile powders for reconstitution into sterile injectable solutions or dispersions just prior to use. Examples of suitable aqueous and nonaqueous carriers, diluents, solvents or vehicles include water, ethanol, polyols (such as glycerol, propylene glycol, polyethylene glycol, and the like), and suitable mixtures thereof, vegetable oils (such as olive oil), and injectable organic esters such as ethyl oleate. Proper
20 fluidity can be maintained, for example, by the use of coating materials such as lecithin, by the maintenance of the required particle size in the case of dispersions, and by the use of surfactants. Conversely, reduced particle size may maintain biological activity.

These compositions may also contain adjuvants such as preservative, wetting agents, emulsifying agents, and dispersing agents. Prevention of the action of microorganisms may
25 be ensured by the inclusion of various antibacterial and antifungal agents, for example, paraben, chlorobutanol, phenol sorbic acid, and the like. It may also be desirable to include isotonic agents such as sugars, sodium chloride, and the like. Prolonged absorption of the injectable pharmaceutical form may be brought about by the inclusion of agents which delay absorption such as aluminum monostearate and gelatin.

30 In some cases, in order to prolong the effect of the drug, it is desirable to slow the absorption of the drug from subcutaneous or intramuscular injection. This may be accomplished by the use of a liquid suspension of crystalline or amorphous material with poor water solubility. The rate of absorption of the drug then depends upon its rate of dissolution which, in turn, may depend upon crystal size and crystalline form.
35 Alternatively, delayed absorption of a parenterally administered drug form is accomplished by dissolving or suspending the drug in an oil vehicle.

Injectable depot forms are made by forming microencapsule matrices of the drug in biodegradable polymers such as polylactide-polyglycolide. Depending upon the ratio of

drug to polymer and the nature of the particular polymer employed, the rate of drug release can be controlled. Examples of other biodegradable polymers include poly(orthoesters) and poly(anhydrides) Depot injectable formulations are also prepared by entrapping the drug in liposomes or microemulsions which are compatible with body tissues.

5 The injectable formulations can be sterilized, for example, by filtration through a bacterial-retaining filter, or by incorporating sterilizing agents in the form of sterile solid compositions which can be dissolved or dispersed in sterile water or other sterile injectable medium just prior to use.

10 Solid dosage forms for oral administration include capsules, tablets, pills, powders, and granules. In such solid dosage forms, the active compound is mixed with at least one inert, pharmaceutically acceptable excipient or carrier such as sodium citrate or dicalcium phosphate and/or a) fillers or extenders such as starches, lactose, sucrose, glucose, mannitol, and silicic acid, b) binders such as, for example, carboxymethylcellulose, alginates, gelatin, polyvinylpyrrolidone, sucrose, and acacia, c) humectants such as glycerol, d) disintegrating
15 agents such as agar-agar, calcium carbonate, potato or tapioca starch, alginic acid, certain silicates, and sodium carbonate, e) solution retarding agents such as paraffin, f) absorption accelerators such as quaternary ammonium compounds, g) wetting agents such as, for example, cetyl alcohol and glycerol monostearate, h) absorbents such as kaolin and bentonite clay, and i) lubricants such as talc, calcium stearate, magnesium stearate, solid
20 polyethylene glycols, sodium lauryl sulfate, and mixtures thereof. In the case of capsules, tablets and pills, the dosage form may also comprise buffering agents.

Solid compositions of a similar type may also be employed as fillers in soft and hard-filled gelatin capsules using such excipients as lactose or milk sugar as well as high molecular weight polyethylene glycols and the like.

25 The solid dosage forms of tablets, dragees, capsules, pills, and granules can be prepared with coatings and shells such as enteric coatings and other coatings well known in the pharmaceutical formulating art. They may optionally contain opacifying agents and can also be of a composition that they release the active ingredient(s) only, or preferentially, in a certain part of the intestinal tract, optionally, in a delayed manner. Examples of embedding
30 compositions which can be used include polymeric substances and waxes.

The active compounds can also be in micro-encapsulated form, if appropriate, with one or more of the above-mentioned excipients.

35 Liquid dosage forms for oral administration include pharmaceutically acceptable emulsions, solutions, suspensions, syrups and elixirs. In addition to the active compounds, the liquid dosage forms may contain inert diluents commonly used in the art such as, for example, water or other solvents, solubilizing agents and emulsifiers such as ethyl alcohol, isopropyl alcohol, ethyl carbonate, ethyl acetate, benzyl alcohol, benzyl benzoate, propylene glycol, 1,3-butylene glycol, dimethyl formamide, oils (in particular, cottonseed, groundnut,

corn, germ, olive, castor, and sesame oils), glycerol, tetrahydrofurfuryl alcohol, polyethylene glycols and fatty acid esters of sorbitan, and mixtures thereof.

Besides inert diluents, the oral compositions can also include adjuvants such as wetting agents, emulsifying and suspending agents, sweetening, flavoring, and perfuming agents.

Suspensions, in addition to the active compounds, may contain suspending agents as, for example, ethoxylated isostearyl alcohols, polyoxyethylene sorbitol and sorbitan esters, microcrystalline cellulose, aluminum metahydroxide, bentonite, agar-agar, and tragacanth, and mixtures thereof.

Compositions for rectal or vaginal administration are preferably suppositories which can be prepared by mixing the compounds of this invention with suitable non-irritating excipients or carriers such as cocoa butter, polyethylene glycol or a suppository wax which are solid at room temperature but liquid at body temperature and therefore melt in the rectum or vaginal cavity and release the active compound.

Compounds of the present invention can also be administered in the form of liposomes. As is known in the art, liposomes are generally derived from phospholipids or other lipid substances. Liposomes are formed by mono- or multi-lamellar hydrated liquid crystals that are dispersed in an aqueous medium. Any non-toxic, physiologically acceptable and metabolizable lipid capable of forming liposomes can be used. The present compositions in liposome form can contain, in addition to a compound of the present invention, stabilizers, preservatives, excipients, and the like. The preferred lipids are the phospholipids and the phosphatidyl cholines (lecithins), both natural and synthetic.

Methods to form liposomes are known in the art. See, for example, Prescott, Ed., Methods in Cell Biology, Volume XIV, Academic Press, New York, N.Y. (1976), p. 33 et seq.

Dosage forms for topical administration of a compound of this invention include powders, sprays, ointments and inhalants. The active compound is mixed under sterile conditions with a pharmaceutically acceptable carrier and any needed preservatives, buffers, or propellants which may be required. Ophthalmic formulations, eye ointments, powders and solutions are also contemplated as being within the scope of this invention.

Actual dosage levels of active ingredients in the pharmaceutical compositions of this invention may be varied so as to obtain an amount of the active compound(s) that is effective to achieve the desired therapeutic response for a particular patient, compositions, and mode of administration. The selected dosage level will depend upon the activity of the particular compound, the route of administration, the severity of the condition being treated, and the condition and prior medical history of the patient being treated. However, it is within the skill of the art to start doses of the compound at levels lower than required for to achieve the desired therapeutic effect and to gradually increase the dosage until the desired

effect is achieved.

Generally, dosage levels of about 1 to about 50 mg/kg/day, more preferably of about 5 to about 25 mg/kg/day of active compound are administered orally to a mammalian patient. If desired, the effective daily dose may be divided into multiple doses for purposes of administration, e.g. two to four separate doses per day.

It is understood that the foregoing detailed description and accompanying examples are merely illustrative and are not to be taken as limitations upon the scope of the invention, which is defined solely by the appended claims and their equivalents. Various changes and modifications to the disclosed embodiments will be apparent to those skilled in the art.

Such changes and modifications, including without limitation those relating to the chemical structures, substituents, derivatives, intermediates, syntheses, formulations and/or methods of use of the invention, may be made without departing from the spirit and scope thereof.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US 02/04501

Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☒ Claims Nos.:
because they relate to subject matter not required to be searched by this Authority, namely:

Although claims 68 - 76 are directed to a method of treatment of the human/animal body, the search has been carried out and based on the alleged effects of the compound/composition.
2. ☐ Claims Nos.:
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
3. ☐ Claims Nos.:
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this International application, as follows:

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
2. ☐ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.
